## 26. Remove Duplicates from Sorted Array

Easy

Favorite

Share

Given a sorted array *nums*, remove the duplicates **in-place** such that each element appear only *once* and return the new length.

Do not allocate extra space for another array, you must do this by **modifying the input array in-place** with  $O(1)$  extra memory.

### Example 1:

Given *nums* = [1,1,2],

Your function should return length = 2, with the first two elements of *nums* being 1 and 2 respectively.

It doesn't matter what you leave beyond the returned length.

### Example 2:

Given *nums* = [0,0,1,1,1,2,2,3,3,4],

Your function should return length = 5, with the first five elements of *nums* being modified to 0, 1, 2, 3, and 4 respectively.

It doesn't matter what values are set beyond the returned length.

### Clarification:

Confused why the returned value is an integer but your answer is an array?

Note that the input array is passed in by **reference**, which means modification to the input array will be known to the caller as well.

Internally you can think of this:

```
// nums is passed in by reference. (i.e., without making a copy)
int len = removeDuplicates(nums);
```

```
// any modification to nums in your function would be known by the caller.
```
